<u>Today</u> Cosmic Background Radiation

http://astroweb.case.edu/ssm/astr328/

<u>Time</u>	Event
$t \sim 10^{-43} { m s}$	Planck scale (<i>speculative</i>)
$t \sim 10^{-38} { m s}$	GUT scale (speculative)
$t \sim 10^{-35} { m s}$	Inflation (speculative)
$t \sim 10^{-12} \text{ s}$	Standard Model forces emerge
$t \sim 10^{-8} { m s}$	WIMPs decouple (speculative)
$t \sim 10^{-5} { m s}$	quarks condense into baryons (baryoge
$t \sim 10^{-4} { m s}$	proton-antiproton annihilation ends
$t \sim 1 \mathrm{s}$	neutrinos decouple
$t \sim 4 \mathrm{s}$	electron-positron annihilation ends
$t \sim 10^2 { m s}$	Big Bang Nucleosynthesis
$t \sim 10^5 \text{ yr}$	Matter-radiation equality
$t \sim 4 \times 10^5 \text{ yr}$	Atoms form, CMB emerges
$t \sim 5 \times 10^6 \text{ yr}$	Gas temperature decouples from radia
$t \sim 10^7 \text{ yr}$	Dark Ages
$t \sim 5 \times 10^8 \text{ yr}$	Cosmic dawn (first stars)
$t \sim 10^9 \text{ yr}$	Galaxies form
$t \sim 4 \times 10^9 \text{ yr}$	Peak star formation
$t \sim 9 \times 10^9 \text{ yr}$	Sun forms
$t \sim 13 \times 10^9 \text{ yr}$	
<u> </u>	

genesis)

iation

Early universe expansion dynamics is radiation dominated

Friedmann equation

$$H^2 = H^2(\Omega_m + \Omega_r + \Omega_k + \Omega_\Lambda)$$

Simplifies to
$$\left(\frac{\dot{a}}{a}\right) = H_0 \Omega_{r_0}^{1/2} a^{-2}$$

for the early, radiation dominated universe.

We also have

$$T \sim a^{-1}$$

So we can replace *a* with *T* and solve for T(t) in place of a(t)

Radiation energy density

$$\rho_{r_0}c^2 = \varepsilon_{r_0} = \alpha T_{r_0}^4$$

$$\Omega_{r_0} = \frac{8\pi G}{3H_0^2} \frac{\varepsilon_{r_0}}{c^2} = \frac{8\pi G}{3H_0^2} \frac{\alpha T_{r_0}^4}{c^2}$$

Early universe expansion dynamics is radiation dominated

Replacing *a* with *T*

$$\frac{\dot{T}}{T} = -\frac{\dot{a}}{a}$$
$$\frac{\dot{T}}{T} = -\sqrt{\frac{8\pi\alpha G}{3c^2}}T^2$$
$$T = \left(\frac{32\pi\alpha G}{3c^2}\right)^{-1/4}t^{1/2} = A$$

 $T^2t = \text{constant}$

during radiation domination. Is just the thermodynamics of adiabatic expansion, depending only on elementary physical constants.

Radiation energy density

$$\rho_{r_0}c^2 = \varepsilon_{r_0} = \alpha T_{r_0}^4$$

$$\Omega_{r_0} = \frac{8\pi G}{3H_0^2} \frac{\varepsilon_{r_0}}{c^2} = \frac{8\pi G}{3H_0^2} \frac{\alpha T_{r_0}^4}{c^2}$$

 $Kt^{1/2}$

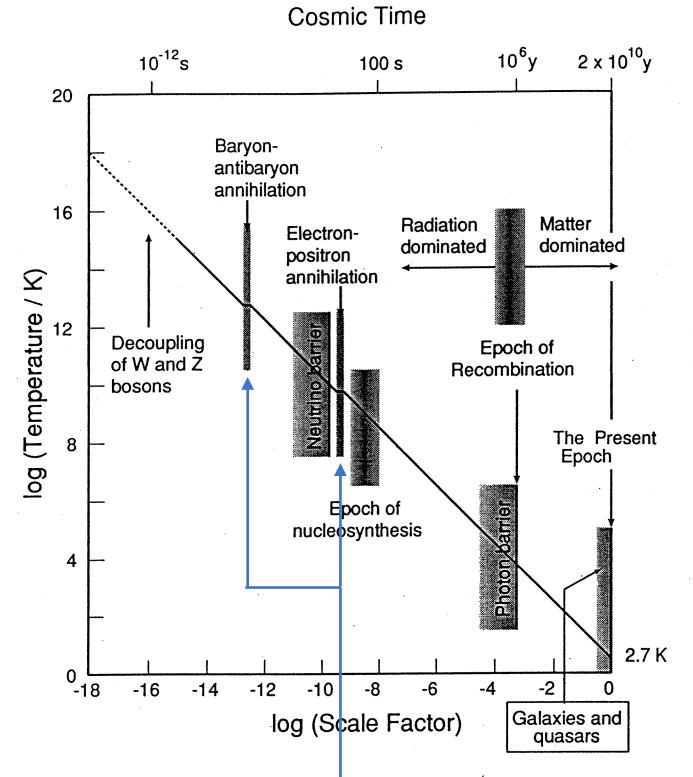

Fig. 6.1 The thermal history of the standard Hot Big Bang. The radiation temperature decreases as $T_r \propto R^{-1}$ except for abrupt jumps as different particle-antiparticle pairs annihilate at $kT \approx mc^2$. Various important epochs in the standard model are indicated. An approximate time scale is indicated along the top of the diagram. The neutrino and photon barriers are indicated. In the standard model, the Universe is optically thick to neutrinos and photons prior to these epochs.

Note the brief pause in the decline of the temperature of the radiation field as first protonantiproton annihilation, then later electron-positron annihilation dump energy into radiation.

<u>Time</u>	Event	

neutrinos decouple $t \sim 1 \text{ s}$

neutrinos drop out of equilibrium as photons will later do. They lose energy with expansion the same as the radiation field, $T_{\nu} \sim a^{-1}$, with an initial energy density $\varepsilon_{\nu} \sim T_{\nu}^{4}$ fixed at this point.

 $t \sim 4 \text{ s}$ electron-positron annihilation ends

Being less massive than protons, electrons freeze out from positrons at this later time. The excess energy feeds the radiation background but not the neutrino background.

$$K = 0.95 \times 10^{10} \text{ K s}^{1/2}$$

before electron-positron freeze-out

 $K = 1.3 \times 10^{10} \text{ K s}^{1/2}$

after electron-positron freeze-out

 $T = Kt^{1/2}$

$K = 0.95 \times 10^{10} \text{ K s}^{1/2}$

before electron-positron freez

$K = 1.3 \times 10^{10} \text{ K s}^{1/2}$

after electron-positron freeze

Electron-positron freeze-out dumps a bit of extra entropy into the radiation field. Since neutrinos have already decoupled, they compose a radiation field that does not receive this extra bit of heating. Therefore one expects both a cosmic [microwave] background and a cosmic neutrino background of slightly different temperatures:

$$\frac{T_{\nu}}{T_{\gamma}} = \left(\frac{g_1}{g_2}\right)^{1/3} = \left(\frac{4}{11}\right)^{1/3}$$

 $T_{\nu_0} = 1.95 \text{ K}$ when $T_{\gamma_0} = 2.75 \text{ K}$

The existence of a cosmic neutrino background of this specific temperature is a major outstanding prediction of the Hot Big Bang.

	<u>Time</u>	<u>Event</u>	
	$t \sim 1 \text{ s}$	neutrinos decouple	
eze-out	neutrinos drop out of equilibrium as photons will later do. They lose energy with expansion the same as the radiation field, $T_{\nu} \sim a^{-1}$, with an initial energy density $\varepsilon_{\nu} \sim T_{\nu}^{4}$		
ze-out	fixed at this		

 $t \sim 4 \text{ s}$ electron-positron annihilation ends

Being less massive than protons, electrons freeze out from positrons at this later time. The excess energy feeds the radiation background but not the neutrino background.

photons only photons plus neutrinos

$$g_1 = 2$$
; $g_2 = 2 + 2\frac{7}{8} + 2\frac{7}{8}$
bosons bosons + fermions

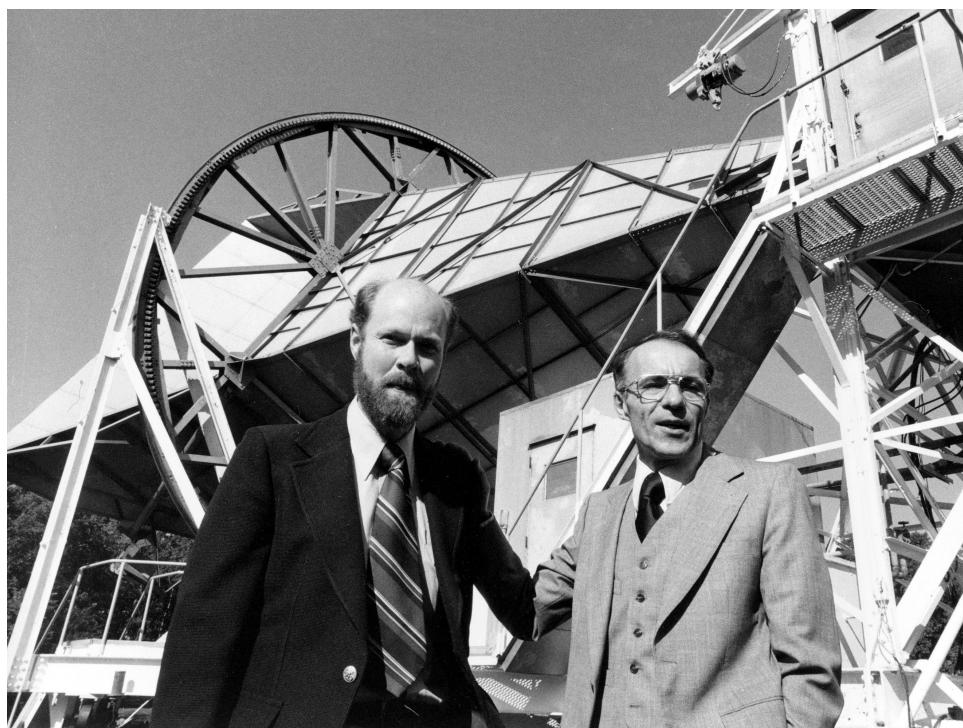

Cosmic Microwave Background

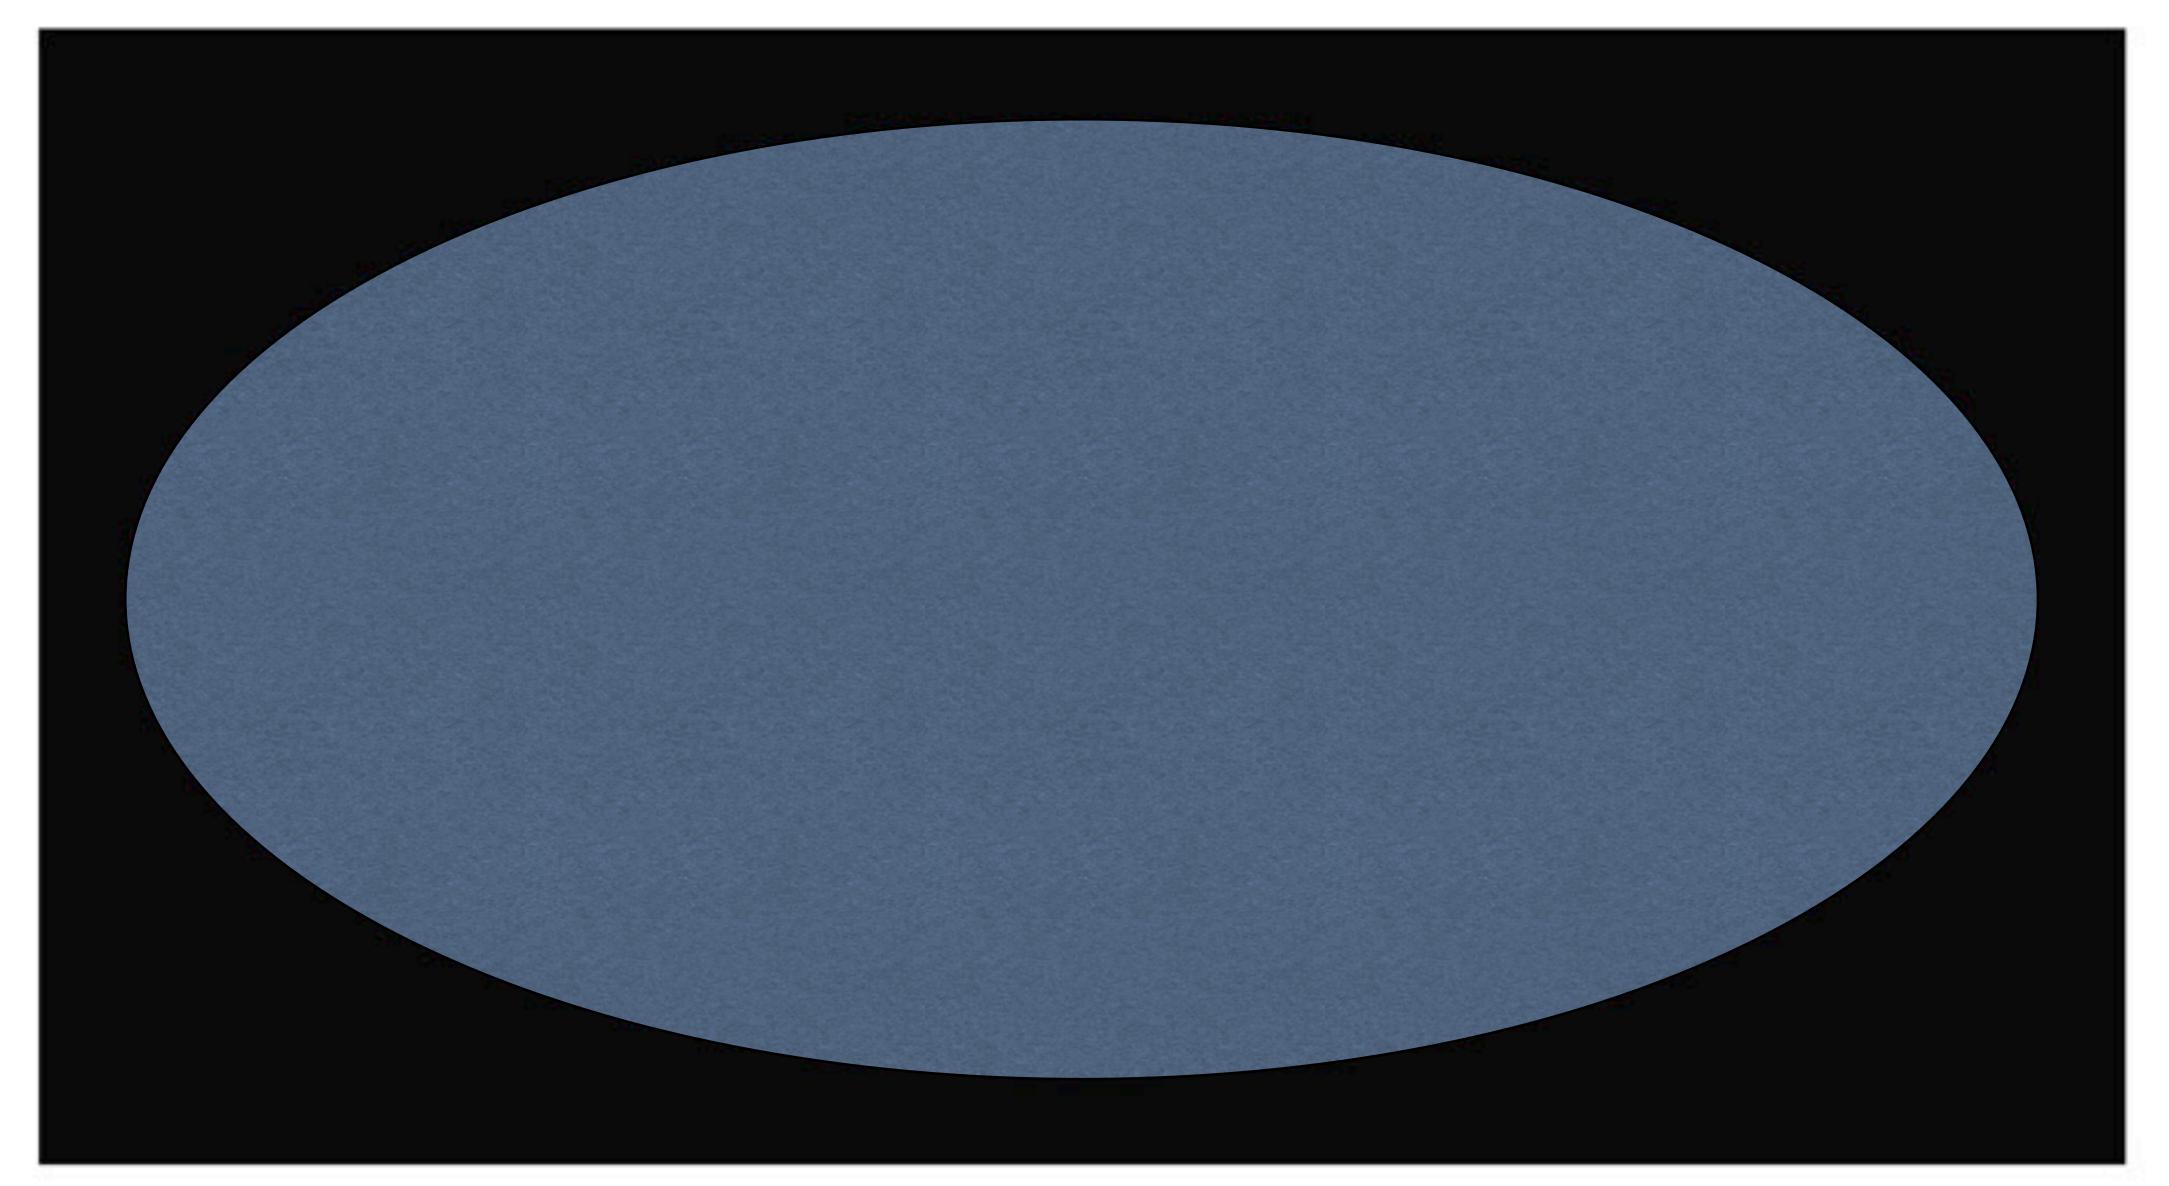

The Cosmic Microwave Background (CMB) is the relic radiation field of the Hot Big Bang. It has an essentially a perfect thermal spectrum with a current temperature of 2.725 K.

This was higher in the past by (1+z), so T ~ 3,000 K at the epoch of recombination. This is the point at which the high-energy tail of the blackbody distribution no longer had enough photons in excess of 1 Rydberg to keep the universe ionized. The existence of the CMB had been anticipated by Gamow in the '50s, but this was largely forgotten by the '60s. It's predicted existence we rediscovered by Dicke & Peebles, who were actively searching for it when it was accidentally found by Penzias & Wilson.

Penzias & Wilson with the horn they discovered the CMB with at AT&T Bell Labs

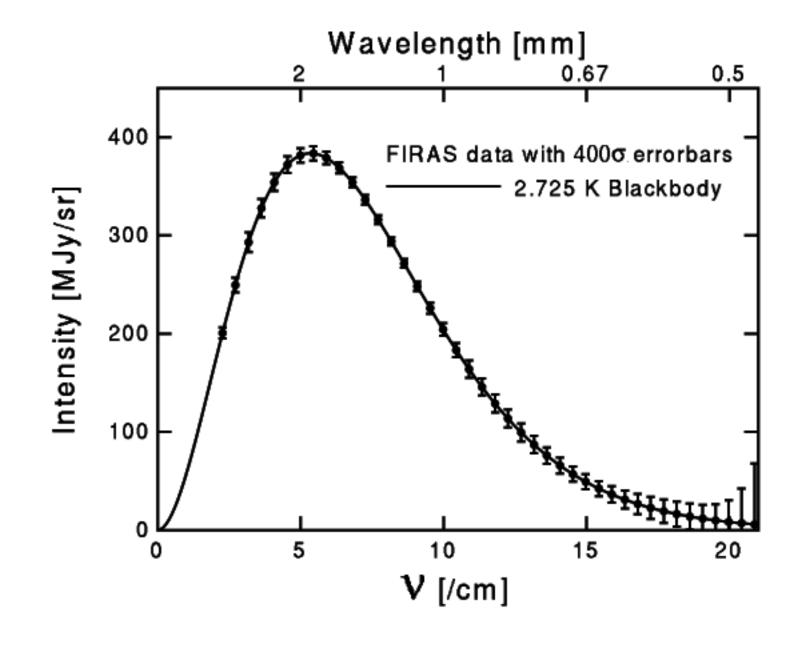

CMB: Baby picture of the universe (380,000 years old)

Same temperature everywhere on the - "monopole"

Cosmic Microwave Background

The Cosmic Microwave Background (CMB) is the relic radiation field of the Hot Big Bang. It has an essentially a perfect thermal spectrum with a current temperature of 2.725 K.

This was higher in the past by (1+z), so T ~ 3,000 K at the epoch of recombination. This is the point at which the high-energy tail of the blackbody distribution no longer had enough photons in excess of 1 Rydberg to keep the universe ionized.

Current temperature
$$T_{\gamma_0} = 2.725 \text{ K}$$

Energy density
$$\varepsilon_{r_0} = \alpha T_{\gamma_0}^4 = 0.261 \text{ MeV m}^{-3}$$

 $\boldsymbol{\alpha}$ is the radiation density constant

Relative to the critical density $\Omega_{r_0} = 5 \times 10^{-5}$ In neutrinos, there's also $\Omega_{\nu_0} = 4 \times 10^{-5}$

Number density of photons

$$n_{\gamma,0} = 411 \text{ cm}^{-3}$$

This greatly exceeds all the photons produced by all the stars throughout the universe over all time.

We observe the CMB as the "surface of last scattering" that occurs at the epoch of recombination. This is the point at which the early universe transitions from an opaque plasma of protons and electrons to a mostly transparent neutral gas of hydrogen and helium.

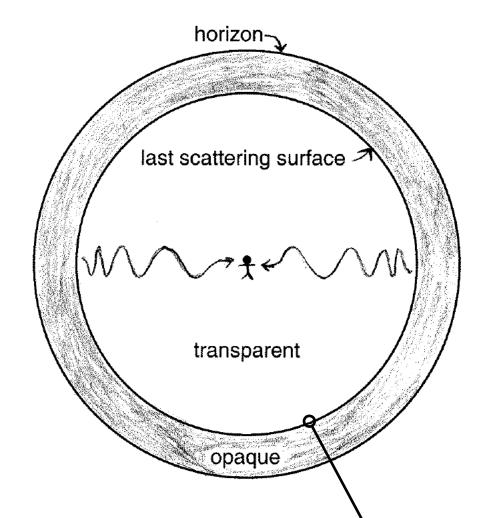

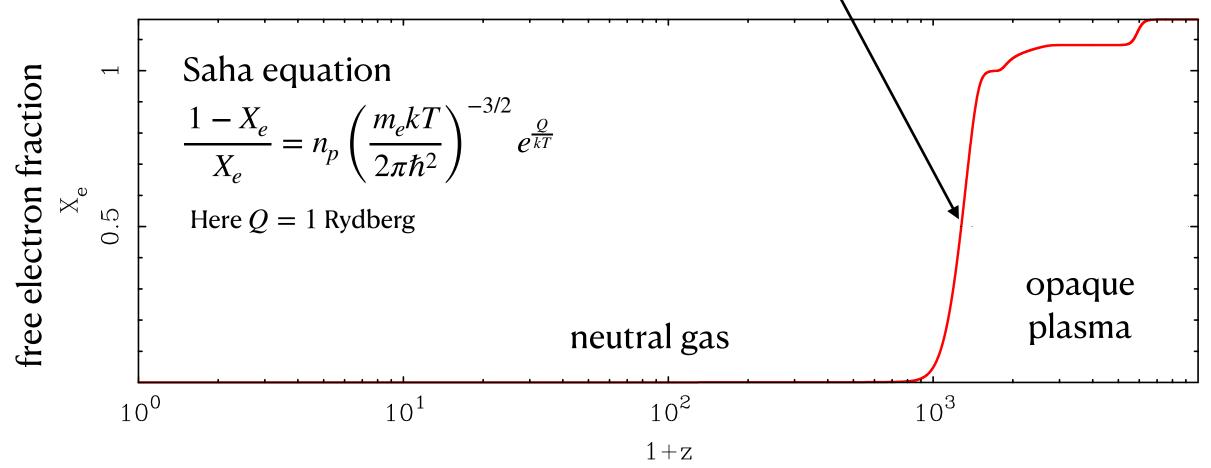

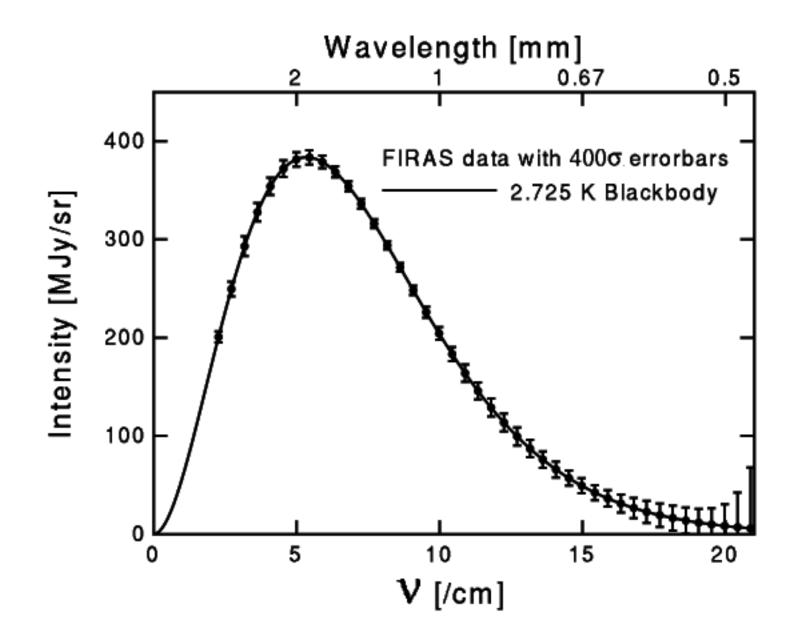

Figure 9.3: An observer is surrounded by a spherical last scattering surface. The photons of the CMB travel straight to us from the last scattering surface, being continuously redshifted.

We observe the CMB as the "surface of last scattering" that occurs at the epoch of recombination. This is the point at which the early universe transitions from an opaque plasma of protons and electrons to a mostly transparent neutral gas of hydrogen and helium.

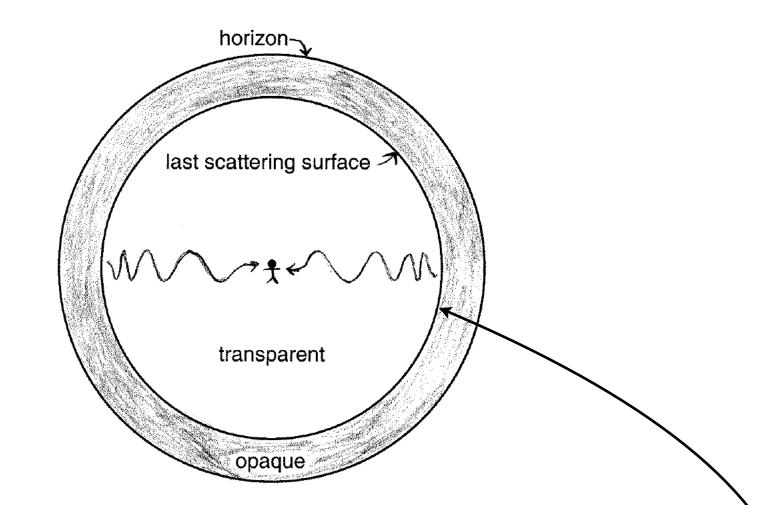

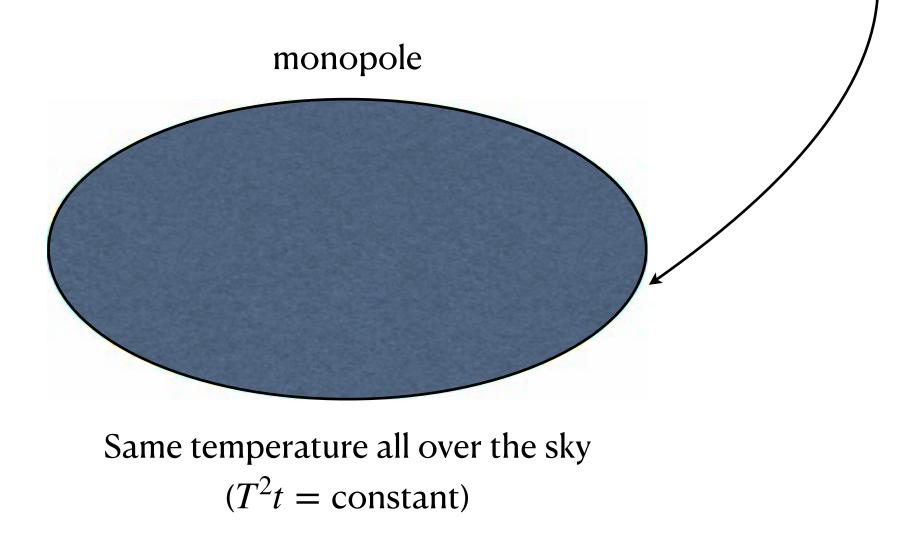

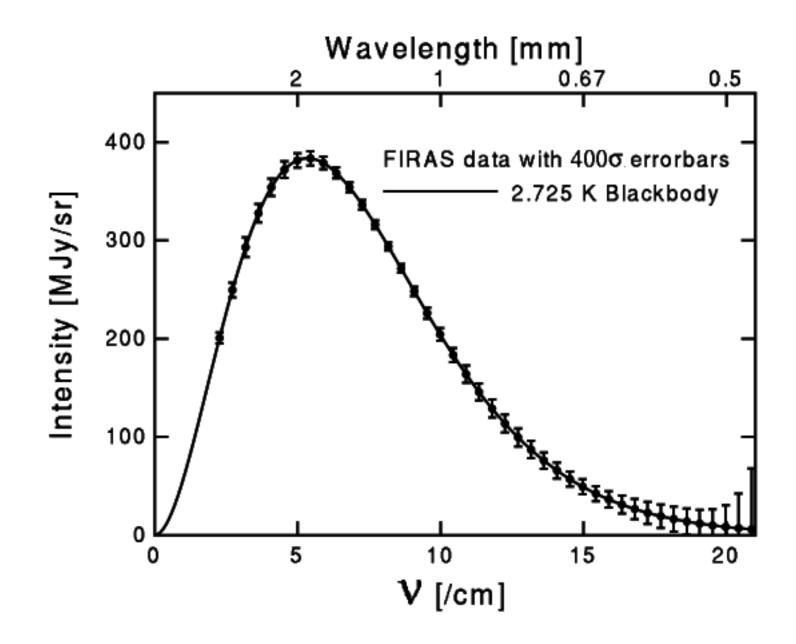

Figure 9.3: An observer is surrounded by a spherical last scattering surface. The photons of the CMB travel straight to us from the last scattering surface, being continuously redshifted.

Soon after the discovery of the CMB in the 1960s, it was realized that its temperature couldn't be *perfectly* uniform. A decades-long hunt for fluctuations was launched.

First, there should be some dipole term owing to our peculiar motion with respect the the CMB frame.

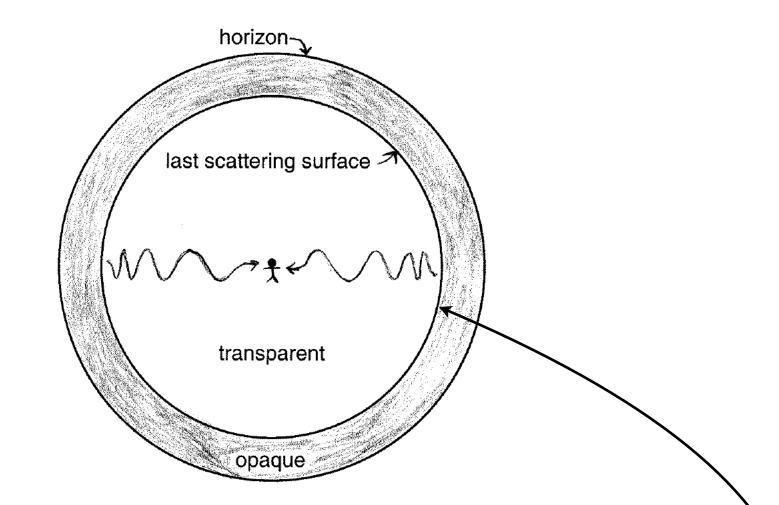

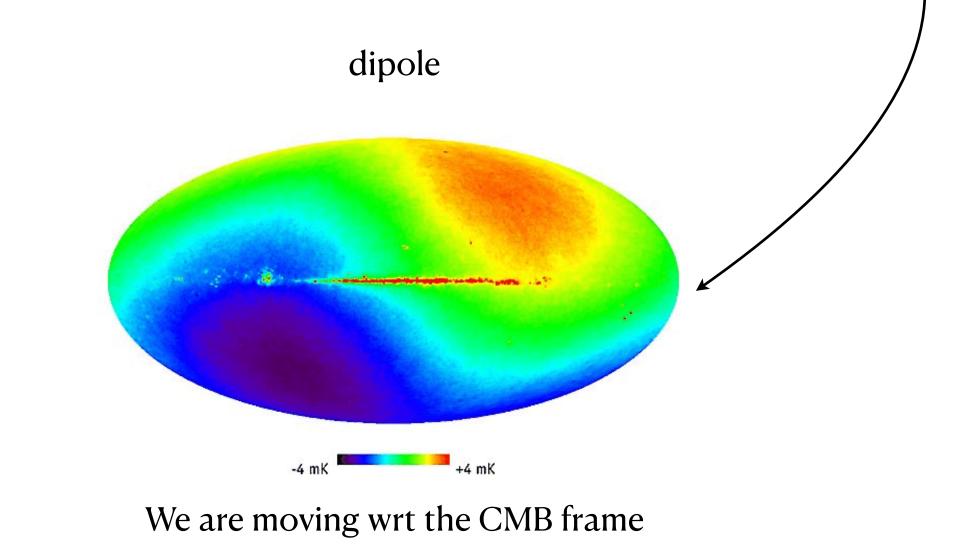

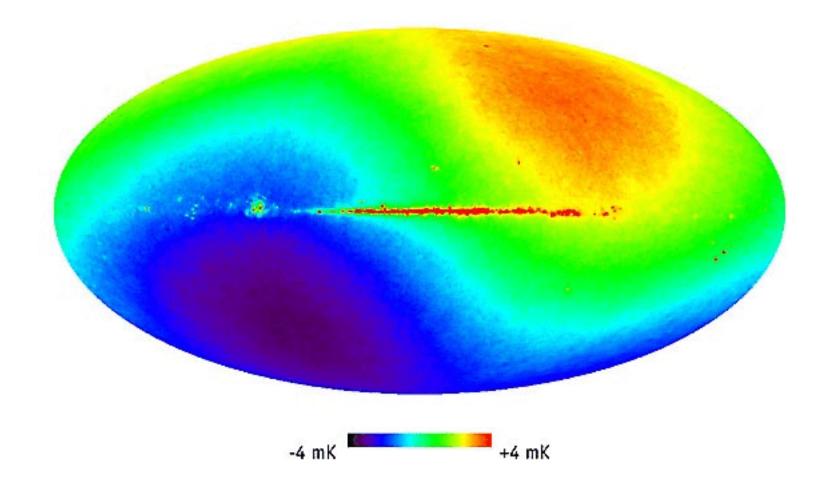

Figure 9.3: An observer is surrounded by a spherical last scattering surface. The photons of the CMB travel straight to us from the last scattering surface, being continuously redshifted.

Dipole

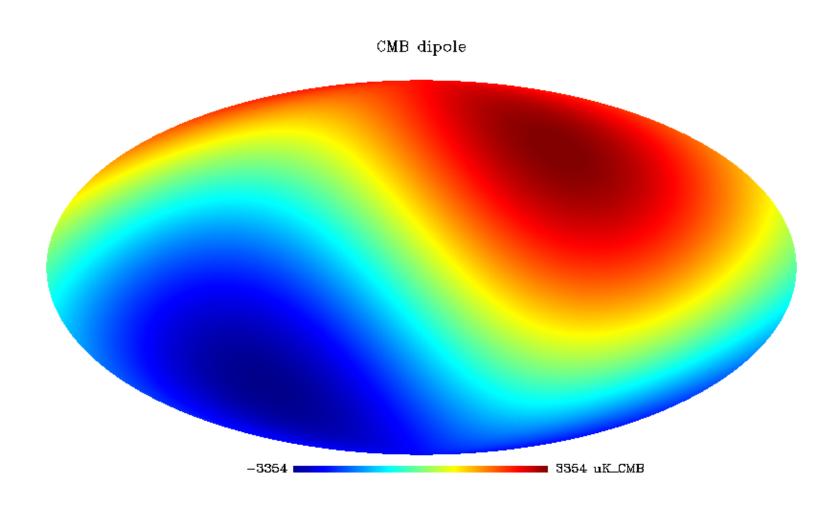

Soon after the discovery of the CMB in the 1960s, it was realized that its temperature couldn't be *perfectly* uniform. A decades-long hunt for fluctuations was launched.

Dipole discovered at the milli-Kelvin scale in the '70s.

For a brief, jaded history of the discovery of the dipole, see http://www.astro.ucla.edu/~wright/CMB-dipole-history.html

Cleaned of foregrounds and smoothed

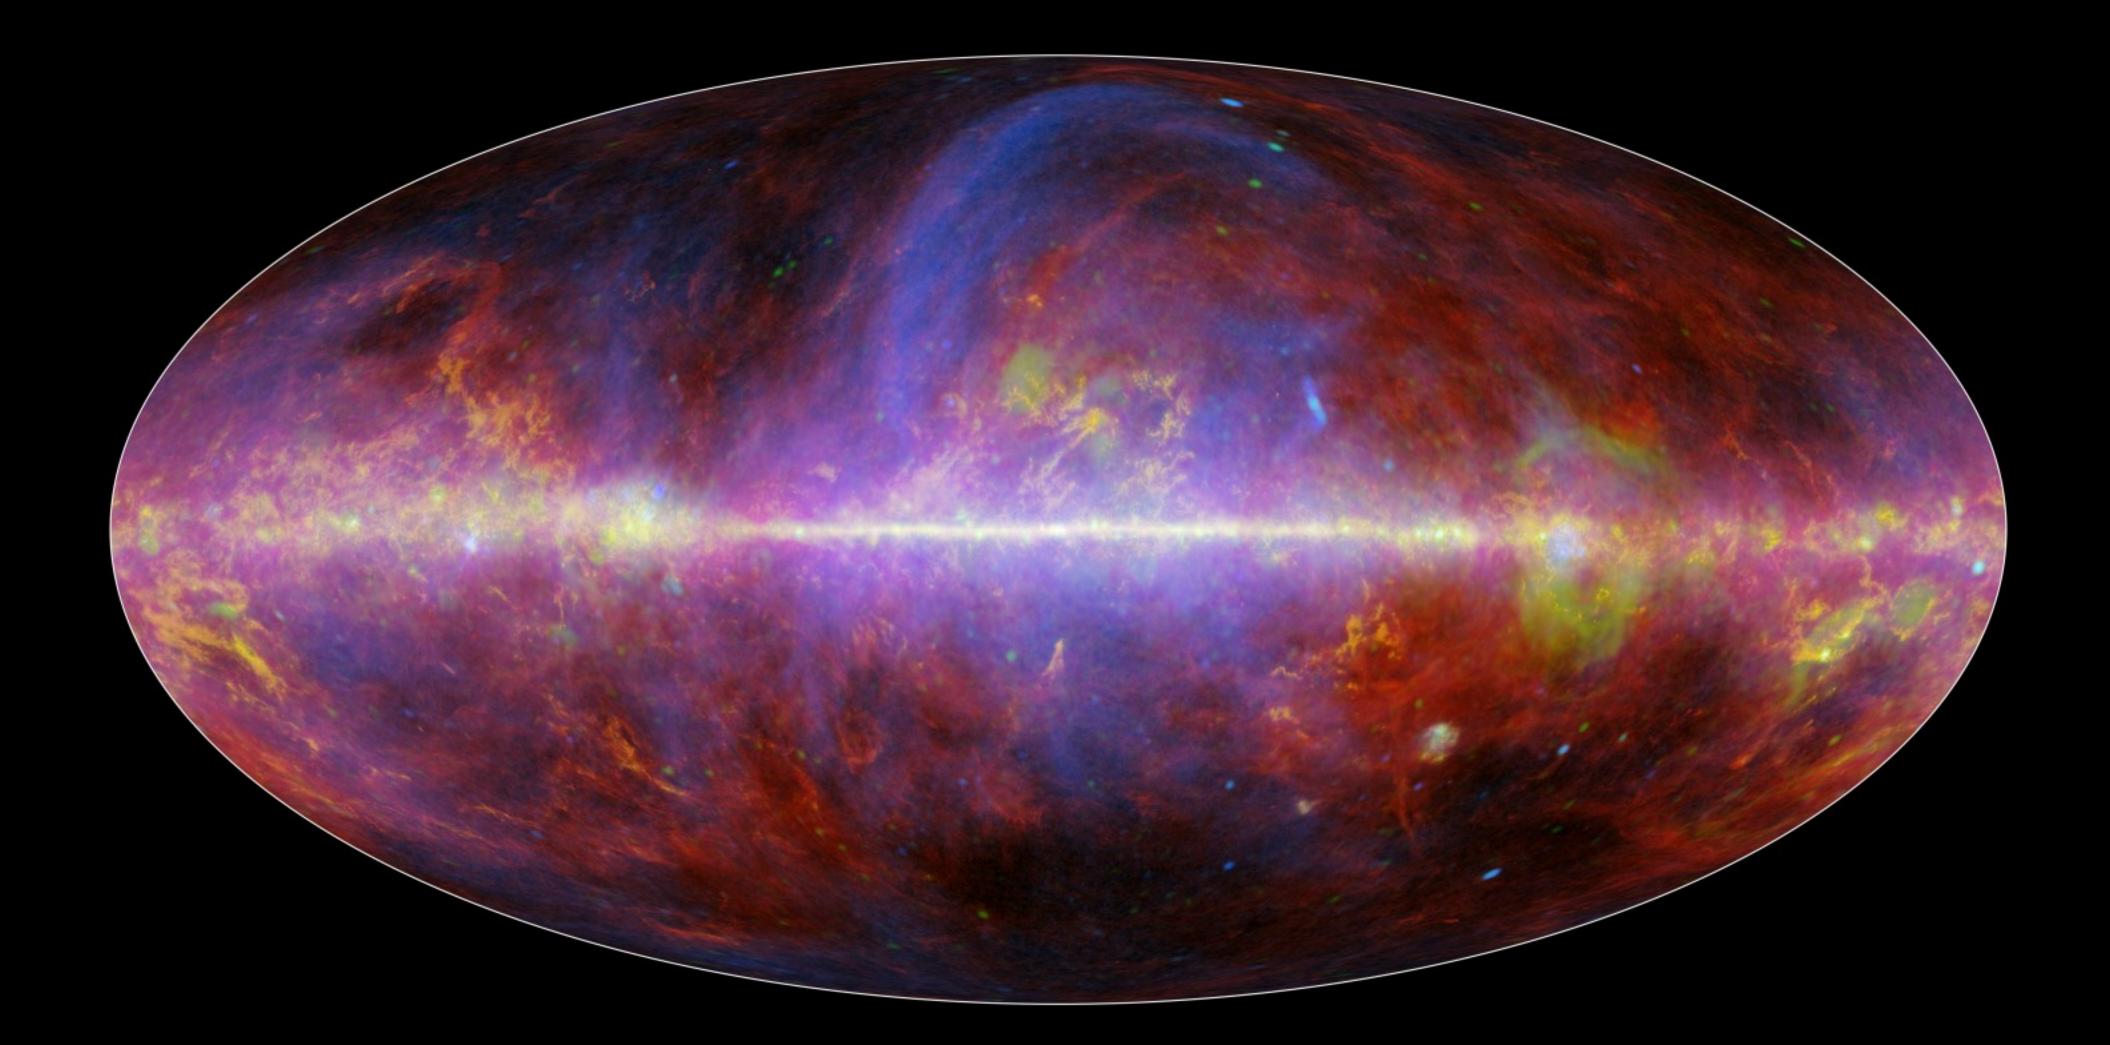

We are moving wrt the CMB frame

3.358 mK amplitude towards $(\ell, b) = (264^\circ, +48^\circ)$

In the frame of the Local Group,

 $V_{\rm LG} = 627 \pm 22 \text{ km s}^{-1}$ towards $(\ell, b) = (276^\circ, +30^\circ)$

That is a disturbingly large peculiar velocity for the Local Group.

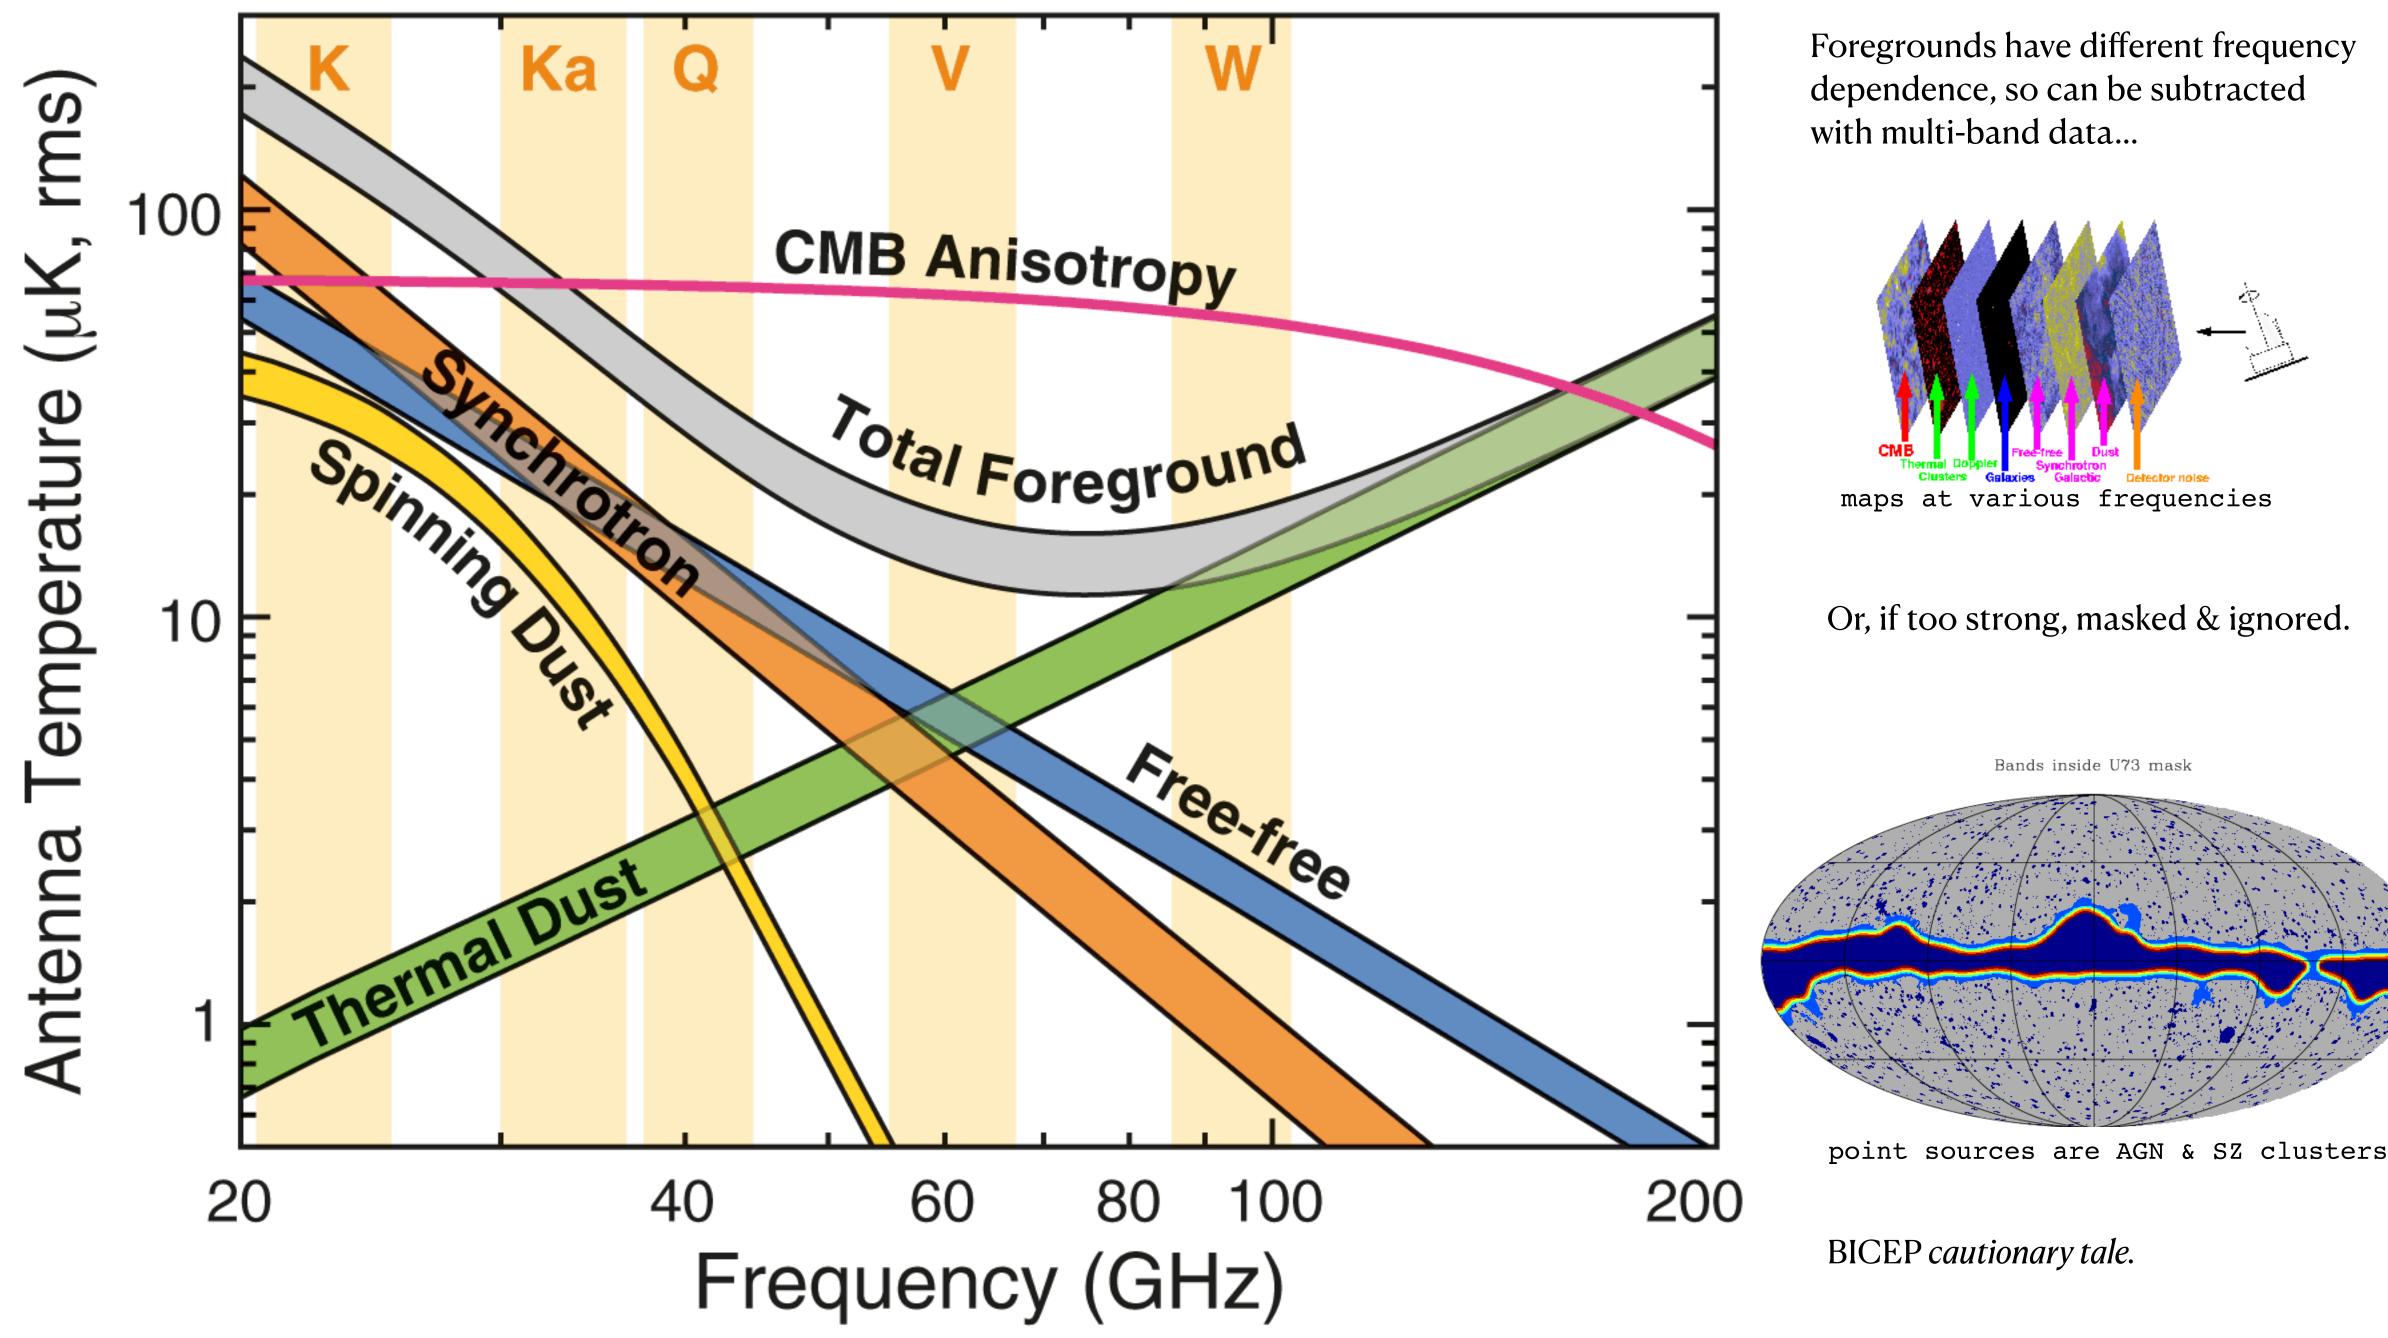

The radio sky has many foreground sources, mostly from our Galaxy, obscuring the cosmic background radiation

The radio sky has many foreground sources, mostly from our Galaxy, obscuring the cosmic background radiation

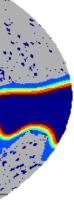

dust (thermal)

free-free radiation

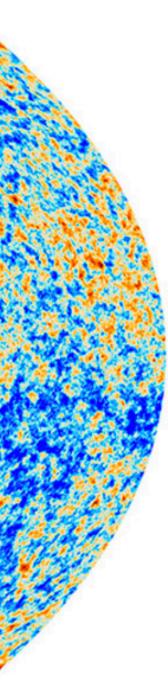

Foregrounds have different frequency

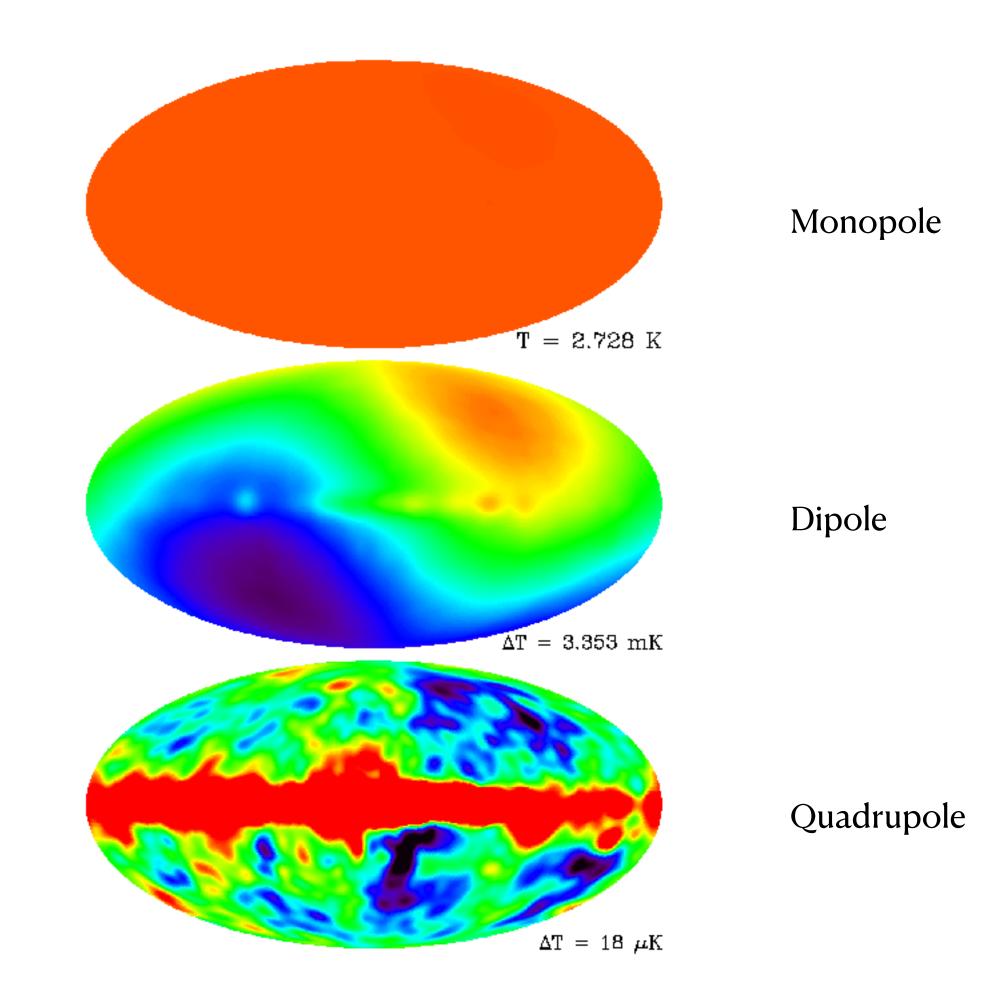

Foreground subtract Planck map

Gain cranked up to show minute fluctuations

Quadrupole

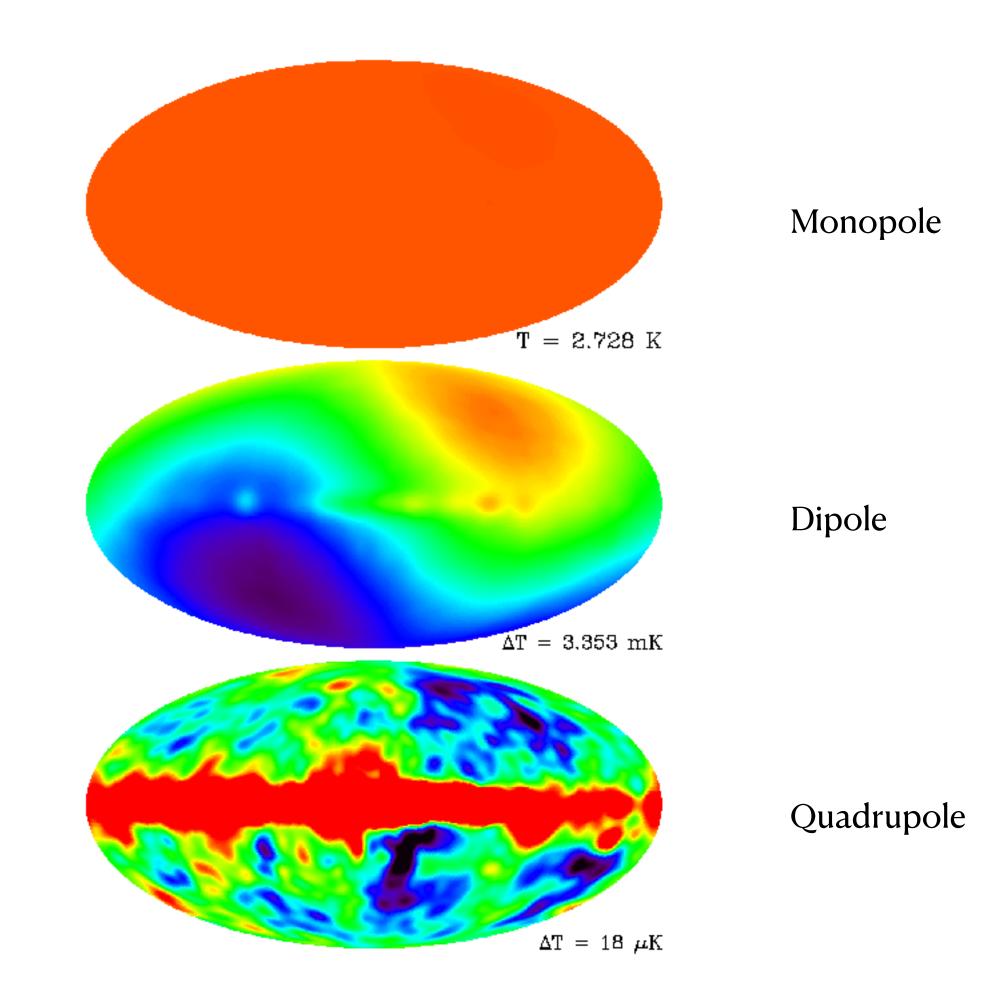

Soon after the discovery of the CMB in the 1960s, it was realized that its temperature couldn't be *perfectly* uniform. A decades-long hunt for fluctuations was launched.

Finding anything beyond the dipole was harder than expected.

Quadrupole finally discovered at the ~10 micro-Kelvin scale by COBE/FIRAS satellite in 1992. (Earned 2006 Physics Nobel prize for John Mather & George Smoot).

$$\frac{\Delta T}{T} = \frac{1.8 \times 10^{-6} \text{ K}}{2.725 \text{ K}} \approx 10^{-5}$$
 observed

Quadrupole

Structure formation basics:

Expect density perturbations $\delta = \frac{\rho - \langle \rho \rangle}{\langle \rho \rangle}$ to grow as $\delta(t) \sim a(t)$.

At z = 0, we observe $\delta \approx 1$ on scales of 8 Mpc. So at z = 1000 we expect $\delta \approx 10^{-3}$ Instead, we observe $\delta \approx 10^{-5}$ off by a factor of 100!

This is a prime motivation for non-baryonic **cold dark matter** — a substance for which perturbations δ can grow sufficiently large while not leaving an imprint of corresponding magnitude on the CMB.

$$\frac{\Delta T}{T} = \frac{1.8 \times 10^{-6} \text{ K}}{2.725 \text{ K}} \approx 10^{-5} \text{ observed}$$

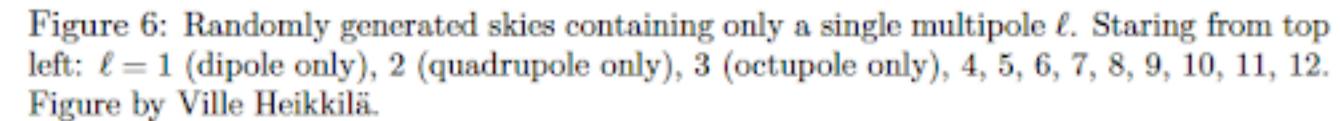

Radiation and baryon plasma tightly coupled at recombination, so a fluctuation in density is reflected by one in temperature.

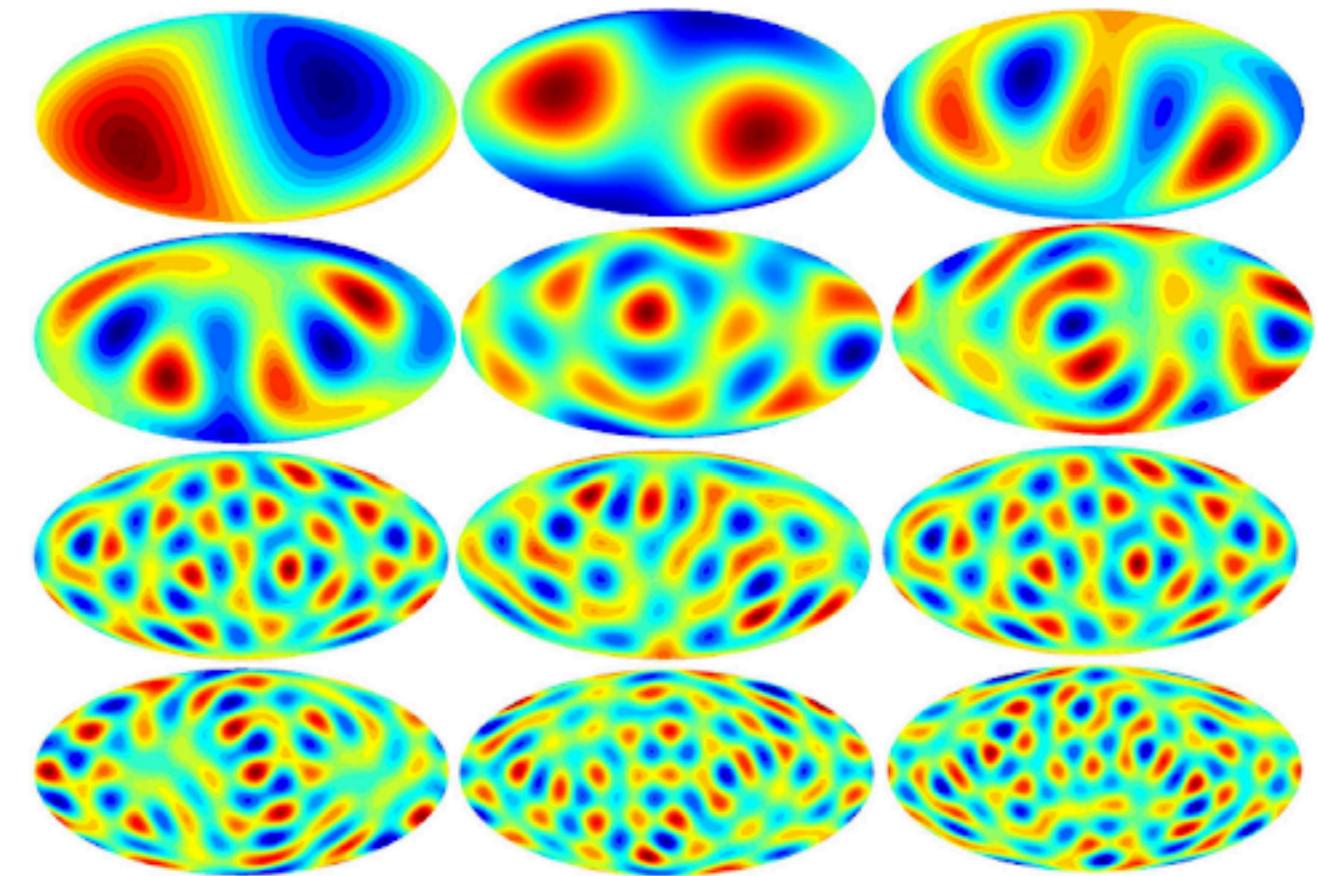

Etc. pole

 $\ell = 1, 2, 3$

 $\ell = 4,5,6$

 $\ell = 7,8,9$

 $\ell = 10, 11, 12$

Spherical harmonics provide a convenient way to decompose the fluctuations observed on the sky

$$\frac{\Delta T}{T}(\theta,\phi) = \sum_{\ell=0}^{\infty} \sum_{m=-\ell}^{\ell} A_{\ell m} Y_{\ell m}$$

with Fourier transform

$$A_{\ell m} = \int_{\text{sky}} \frac{\Delta T}{T} (\theta, \phi) Y^*_{\ell m} d\Omega$$

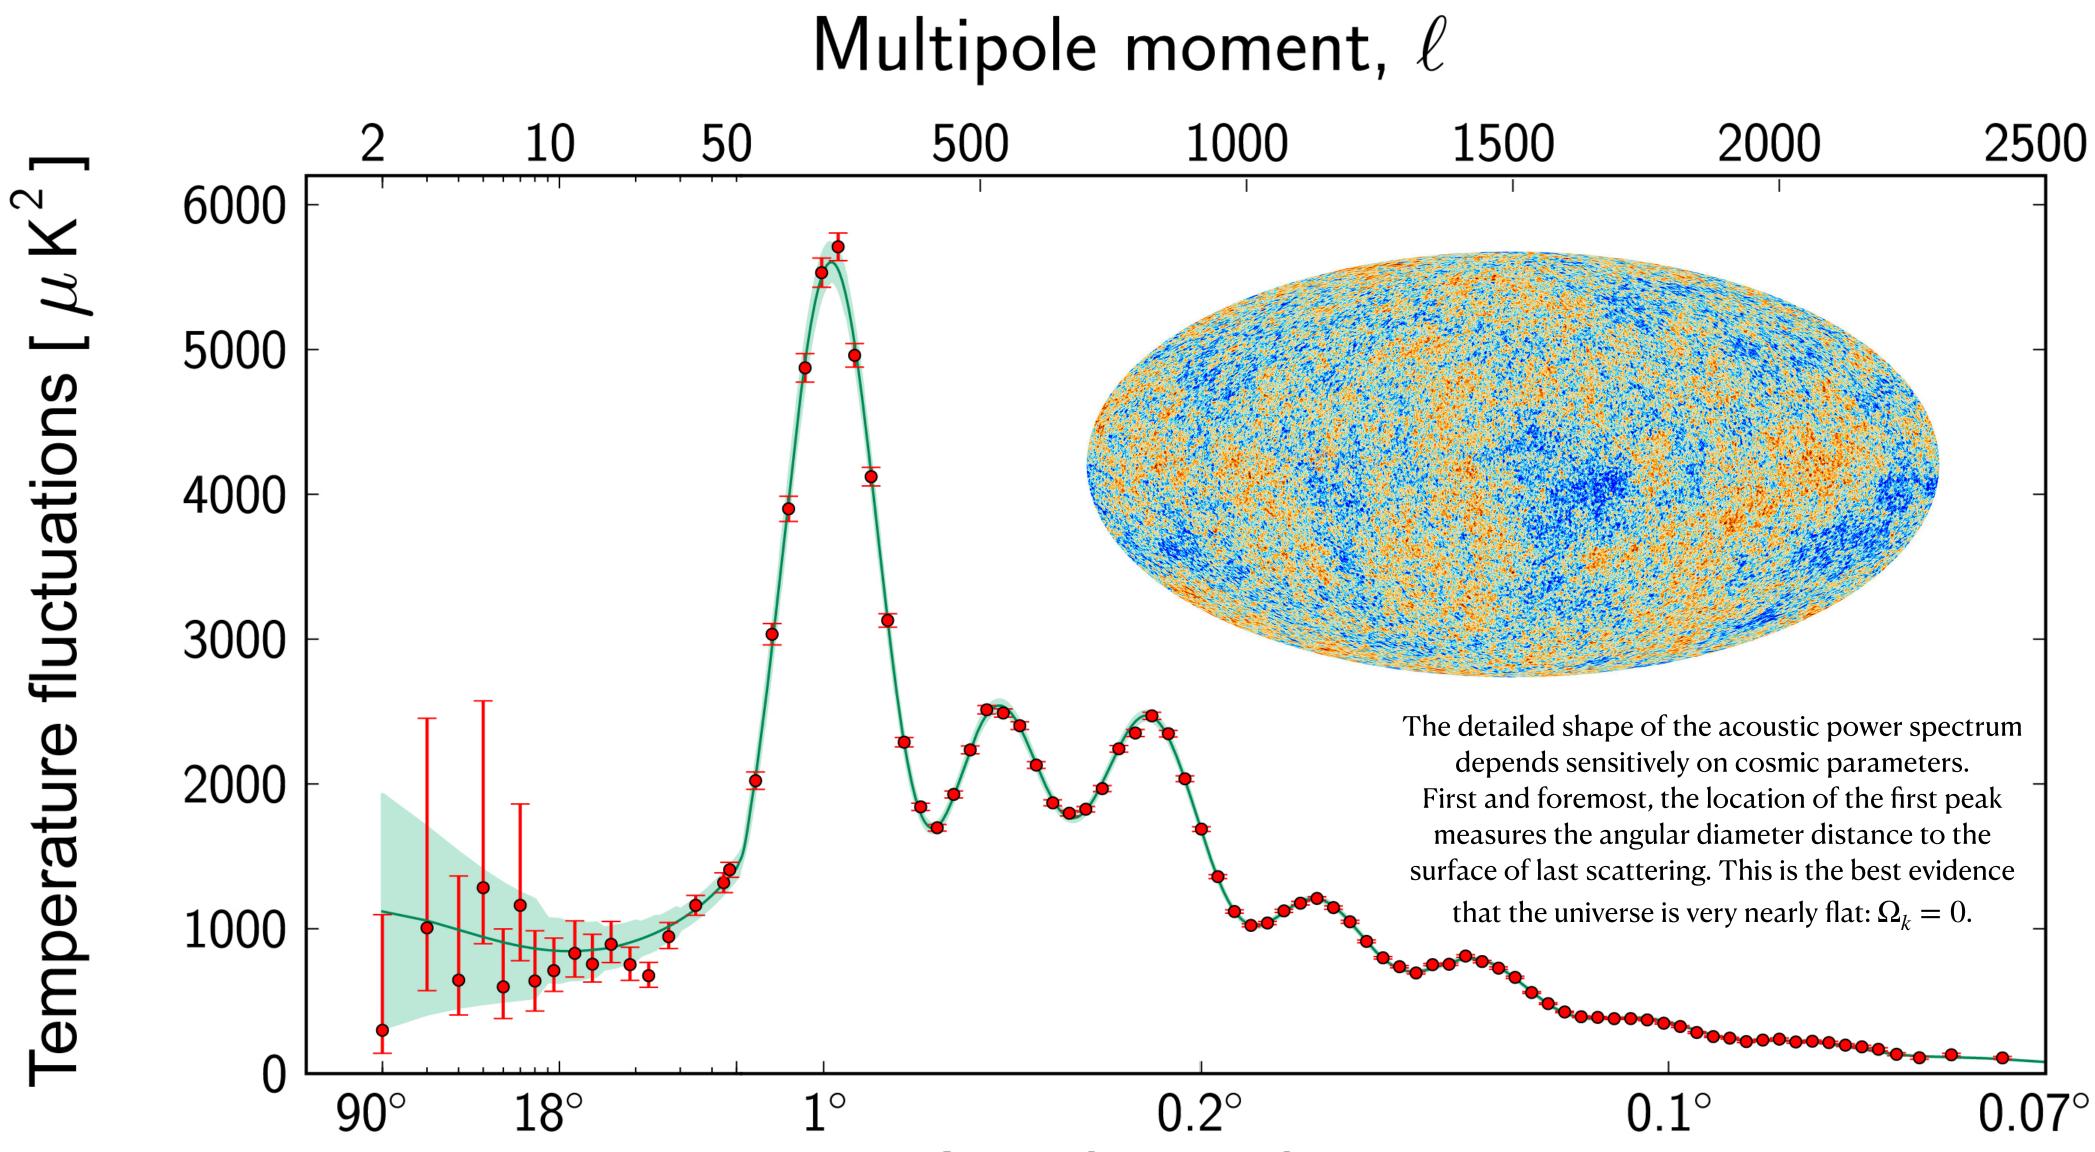

giving the power in fluctuations on an angular scale $\frac{\pi}{\ell}$

$$C_{\ell} = \frac{1}{2\ell + 1} \sum_{m} A_{\ell m} A_{\ell m}^* = \langle |A_{\ell m}|^2 \rangle$$

note: $1^{\circ} = 0.0175$ radians so one degree corresponds to $\frac{\pi}{\ell} = 0.0175$, hence $\ell = 180$. Multipole ℓ varies inversely with angular scale.

The acoustic power spectrum of the CMB is a Fourier transform of temperature fluctuations observed on the sky. This quantifies the frequency with which structures of a characteristic scale appear. These correspond to standing waves at the time of last scattering.

Angular scale
