THIS COURSE WILL ADDRESS

SOME GREAT QUESTIONS

OF MODERN PHYSICS & ASTRONOMY:

WHAT IS THE MISSING MASS PROBLEM?

WHAT IS THE DARK MATTER?

IS IT NECESSARY TO MODIFY THE LAW OF GRAVITY?

**AND OFFER A MULTIPLICITY OF ANSWERS,
OF WHICH AT MOST ONE CAN BE CORRECT.**

**FIRST WE WILL COVER THE EMPIRICAL EVIDENCE THAT
INDICATES THE EXISTENCE OF MASS DISCREPANCIES**

BULLETIN OF THE ASTRONOMICAL INSTITUTES OF THE NETHERLANDS.

1932 August 17

Volume VI.

No. 238.

COMMUNICATION FROM THE OBSERVATORY AT LEIDEN.

The force exerted by the stellar system in the direction perpendicular to the galactic plane and some related problems, by *J. H. Oort.*

Notations.

- z distance from the galactic plane,
 Z velocity component perpendicular to the galactic plane,
 Z_0 the value of Z for $z = 0$,
 l modulus of a Gaussian component of the distribution of Z (formula (5), p. 253),
 $K(z)$ the acceleration in the direction of z ,
 Δ the star-density,
 ρ the distance of a star from the sun,
 $\Phi(M)$ the number of stars per cubic parsec between $M - \frac{1}{2}$ and $M + \frac{1}{2}$,
 $A(m)$ the number of stars per square degree between $m - \frac{1}{2}$ and $m + \frac{1}{2}$,
 b galactic latitude,
 ϖ distance to the axis of rotation of the galactic system,
 δ $\partial \log \Delta / \partial \varpi$.

Summary of the different sections.

4. From VAN RHIJN's tables in *Groningen Publication* No. 38 the density distribution $\Delta(z)$ has been computed for four intervals of visual absolute magnitude (Table 13 and Figure 1). Figures 2 and 3 show $\log \Delta(z)$ for A stars and yellow giants, as derived by LINDBLAD and PETERSSON.

5. With the aid of the data contained in the two preceding sections I have computed the acceleration $K(z)$ between $z = 0$ and $z = 600$. The computations were made by successive approximations; the B stars were eliminated first. The results are in Table 14 and Figure 4, $K'(z)$ giving the values finally adopted. The good agreement between the practically independent values of $K(z)$ derived from the separate absolute magnitude groups is a strong argument in favour of the approximate correctness of the data up to $z = 400$. The result may be summarized by stating that the absolute value of $K(z)$ increases proportionally with z from $z = 0$ to $z = 200$; between $z = 200$ and $z = 500$ it remains practically constant and equal to $3.8 \cdot 10^{-9}$ cm/sec².

Coincidence/flatness problem:
 why is the density parameter of order unity?

Modified Gravity

Dark Matter

Pruning the tree

Baryonic Dark Matter

Many candidates:

brown dwarfs

Jupiters

very faint stars

very cold molecular gas

warm ($\sim 10^5$ K) ionized gas

Can usually figure out a way to detect them: most have been ruled out.

Pruning the tree

Hot Dark Matter (HDM)

Obvious candidate:
neutrinos

neutrinos got mass!...

...but not enough.

Also

- neutrinos suppress structure formation
- can't crowd together closely enough
(phase space constraint)

Pruning the tree

Cold Dark Matter (CDM)

Some new particle, usually assumed to be **WIMPs** (Weakly Interacting Massive Particle) don't interact electromagnetically, so very dark.

Two big motivations:

- 1) total mass outweighs normal mass from BBN
- 2) needed to grow cosmic structure

(I) There's more dark mass than baryons.

From cosmology

$$\Omega_m \approx 6\Omega_b$$

or equivalently, the baryon fraction

$$f_b = 0.17$$

The gravitating mass density exceeds the baryon density from Big Bang Nucleosynthesis (BBN)

(2) There isn't enough time to form the observed cosmic structures from the smooth initial conditions unless there is a component of mass independent of photons.

$$t = 3.8 \times 10^5 \text{ yr}$$

$$t = 1.4 \times 10^{10} \text{ yr}$$

very smooth: $\delta\rho/\rho \sim 10^{-5}$

very lumpy: $\delta\rho/\rho \sim 1$

$$\delta\rho/\rho \propto t^{2/3}$$

These considerations made CDM the dominant paradigm

Only requirement to be CDM is

- dynamically cold (slow moving)
- non-baryonic (no E&M interactions)

could be
WIMPS

(or some other particle)

or

Black Holes

(masses of $\sim 10^5 M_{\odot}$ conceivable)

WIMPs are considered the odds-on favorite CDM candidate because of the so-called 'WIMP miracle': the relic density of a new weakly interacting particle is about right to explain the mass density.

THE WIMP MIRACLE

In the very early universe

- Assume a new (heavy) particle X is initially in thermal equilibrium

- Its relic density is

$$\Omega_X \propto \frac{1}{\langle \sigma v \rangle} \sim \frac{m_X^2}{g_X^4}$$

- $m_X \sim 100 \text{ GeV}, g_X \sim 0.6 \rightarrow \Omega_X \sim 0.1$

- Remarkable coincidence: particle physics independently predicts particles with the right density to be dark matter ***IF*** the predicted new particles exist

Lots of particle candidates for CDM:

WIMPs

Axions

Light dark matter

wimpzillas

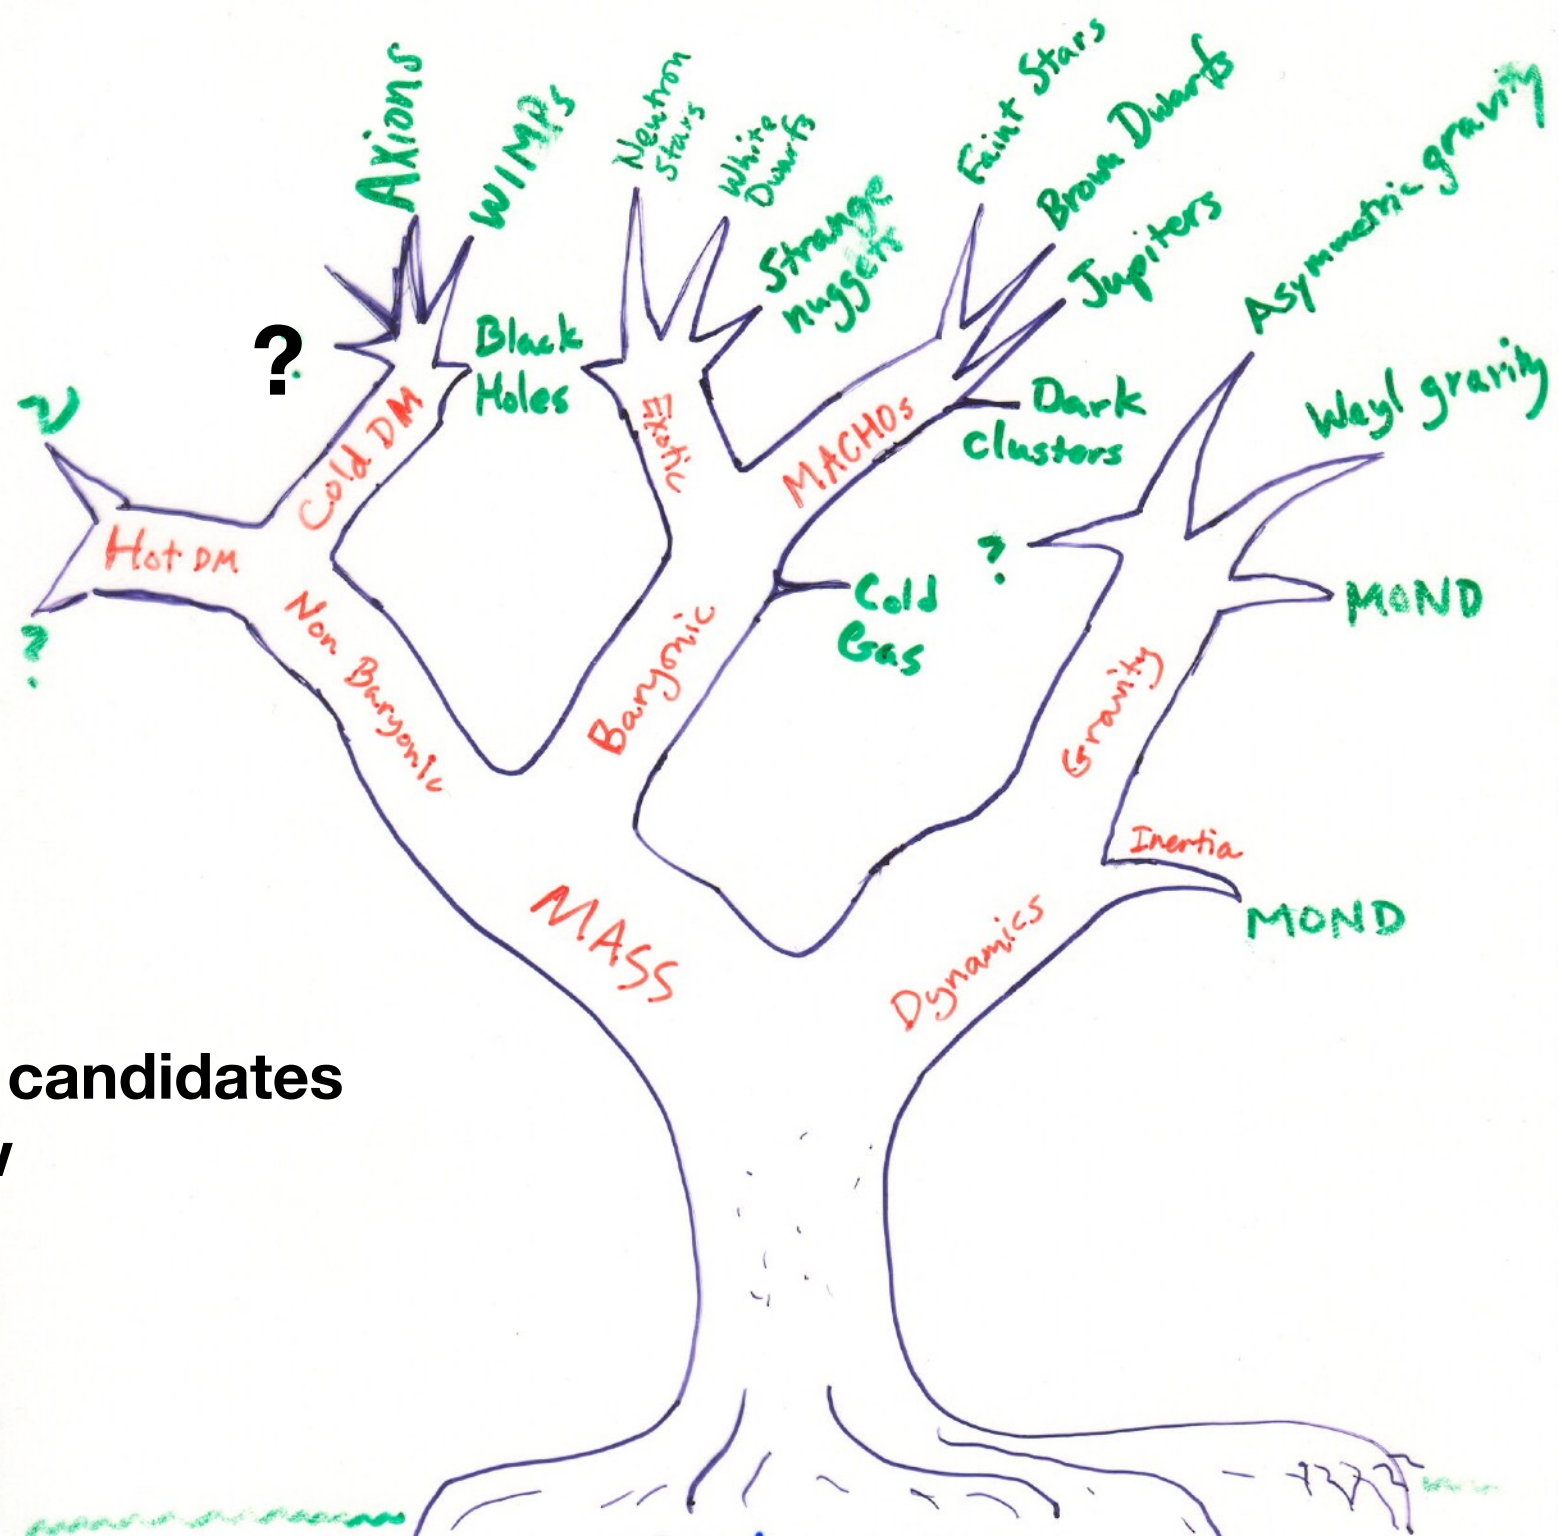

etc.

Can imagine other candidates as well:

Warm DM

Self-interacting DM

etc.

Indeed, the list of candidates continues to grow
