- Jovian planets
- moons of the Jovian planets

## Global Wind Patterns

- Heat transport
- Global winds blow in distinctive patterns:
- Equatorial: E to W
- Mid-latitudes: W to E
- High latitudes: E to W

## Circulation Cells: No Rotation

- Heated air rises at equator.
- Cooler air descends at poles.
- Without rotation, these motions would produce two large circulation cells.

## Circulation Cells with Rotation

- Coriolis effect deflects north-south winds into east-west winds.
- Deflection breaks each of the two large "norotation" cells into three smaller cells in each hemisphere.
- Tropical
- Mid-latitude
- Polar

## Coriolis Effect

- Conservation of angular momentum causes a ball's apparent path on a spinning platform to change direction.

## Prevailing Winds

- Prevailing surface winds at mid-latitudes blow from W to E because the Coriolis effect deflects the S to N surface flow of mid-latitude circulation cells.

## Coriolis Effect on Earth

a Low-pressure regions ("L") draw in air from surrounding areas, and the Coriol is effect causes this air to circulate counterclockwise in the Northern Hemisphere and clockwise in the Southern Hemisphere.

- Air moving from a pole to the equator is going farther from Earth's axis and begins to lag behind Earth's rotation.
- Air moving from the equator to a pole moves closer to the axis and travels ahead of Earth's rotation.

## Coriolis Effect on Earth

- Conservation of angular momentum causes large storms to swirl.
- Direction of circulation depends on hemisphere:
- N : counterclockwise
- right hand rule
- S: clockwise

b This photograph shows the opposite directions of storm circulation in the two hemispheres.
- Giant planets
- Jupiter
- Saturn
- Uranus
- Neptune

Note horizontal bands These are circulation cells Jovian day: 9h 56m

## The Giant Planets

- Jupiter, Saturn, Uranus, and Neptune are the giant planets.
- Jupiter and Saturn: mainly hydrogen and helium (like the sun).
- Hundreds of Earth masses
- Called gas giants.
- Uranus and Neptune: more water, water ice, and other ices
- Tens of Earth masses
- Called ice giants

## Giant Planet Composition

- Jupiter and Saturn
- Mostly H and He gas
- these are the most common elements in the Universe
- similar in composition to the sun
- "Gas Giants"
- Uranus and Neptune
- Mostly hydrogen compounds: water $\left(\mathrm{H}_{2} \mathrm{O}\right)$, methane $\left(\mathrm{CH}_{4}\right)$, ammonia $\left(\mathrm{NH}_{3}\right)$
- Some H, He, and rock
- "Ice Giants"

## Jupiter

# Many astronomers now distinguish between 

Gas Giants Jupiter, Saturn and

## Ice Giants

Uranus, Neptune

## Expect more distinctions with new discoveries

Neptune to scale
Earth to scale

## Sizes of Jovian Planets

- Planets get larger as they get more massive
- up to a point...
- Planets more massive than Jupiter are expected to shrink.
- There comes a point when gravity wins: adding more mass causes contraction.

show Jovian Planet shapes

## Interiors of Jovian Planets

## Inside Jupiter

- High pressure inside of Jupiter causes the phase of hydrogen to change with depth.
- Hydrogen acts like a metal at great depths because its electrons move freely.

## Inside Jupiter

- The core is thought to be made of rock, metals, and hydrogen compounds.
- The core is about the same size as Earth but 10 times as massive.

## Comparing Jovian Interiors

- Models suggest that cores of jovian planets have similar composition.
- Lower pressures inside Uranus and Neptune mean no metallic hydrogen.

## Jupiter's Internal Heat

## Internal Heat of Other Planets

- Saturn also radiates twice as much energy as it receives from the Sun.
- Energy probably comes from differentiation (helium rain).
- Neptune emits nearly twice as much energy as it receives
- also driven by gravitational contraction, but precise mechanism unclear.
- Uranus does not radiate more than it receives.
- no notable internal heat source

## Jupiter's Atmosphere

- Hydrogen compounds in Jupiter form clouds.
- Different cloud layers correspond to freezing points of different hydrogen compounds.
- Other jovian planets have similar cloud layers.

## Jovian Planet Atmospheres

- Other jovian planets have cloud layers similar to Jupiter's.
- Different compounds make clouds of different colors.
- Reveal conditions to different depths in each planet

## temperature

## Jupiter's Colors

- Ammonium sulfide clouds $\left(\mathrm{NH}_{4} \mathrm{SH}\right)$ reflect red/ brown.
- Ammonia, the highest, coldest layer, reflects white.

## Saturn's

## Colors

- Saturn's layers are similar but are deeper in and farther from the Sun - more subdued.

## Methane on Uranus and Neptune

- Methane gas on Neptune and Uranus absorbs red light but reflects blue light.
- Blue light reflects off methane clouds, making those planets look blue.

## Weather on Jovian Planets

- All the jovian planets have strong winds and storms.

The great red spot on Jupiter is a storm larger than Earth that has persisted for centuries.

Polar vortex on Saturn

Polar vortex on Saturn

## Zonal (band) structure in Jovian planet atmospheres

Zonal wind pattern

Hot rising and cool sinking material segregates into band structure

Zonal wind speed

Rapid rotation causes many zones (more than Earth's 3) with high wind speeds show Jovian cloud layers

## Weather on Jovian Planets

- All the jovian planets have strong winds and storms.

## Jovian planets are

- Big
- massive and cold, they can retain light elements like hydrogen and helium

## Jovian planets are

- Big
- massive and cold, they can retain light elements like hydrogen and helium
- their composition is like that of the stars
- the smaller terrestrial planets are the abnormal planets in terms of composition
- Like miniature solar systems
- moons
- rings

## Round objects in the solar system with diameter $<10,000 \mathrm{~km}$

## Selected Moons of the Solar System, with Earth for Scale

## Obvious Definition

- A moon is an object that orbits a planet

## Sizes of Moons

- Small moons (<300 km)
- generally no geological activity
- Medium-sized moons (300-1,500 km)
- Often evidence of some geological activity in past
- Large moons (> 1,500 km)
- Occasional ongoing geological activity

Jupiter

Ganymede

Callisto

## Medium and Large Moons

- Enough self-gravity to be spherical
- Have substantial amounts of ice - as important as rock to overall composition
- Formed in orbit around jovian planets
- Circular orbits mostly in the same direction as the planet rotates... mostly (Triton an exception)

Rocks and metals condense,
hydrogen compounds stay vaporized.
Hydrogen compounds, rocks, . and metals condense.

Inside frost line: terrestrial planets
Beyond frost line: Gas giants, icy moons, dwarf planets, comets

Jupiter

Europa

Callisto

## Medium and

## Large Moons

- Density
- low
- typically $\sim 2 \mathrm{~g} / \mathrm{cc}$
- more than Gas giants
- less than Terrestrials
- Composition
- rock
- ice / subsurface water

Ice is just another common "rock" mineral in the outer solar system.

## Small Moons

- Far more numerous than the medium and large moons
- Not enough gravity to be spherical: "potatoshaped"
- Often just captured asteroids
